Executive Summary

Customer Churn Analytics in European Banking

Prepared from the supplied European_Bank.csv dataset | October 2026

Purpose

Provide a concise, evidence-led summary of churn patterns in the supplied banking customer dataset. This is descriptive analysis and should guide investigation rather than automated decisions.

Headline metrics

• Dataset size: 10,000 records and 14 columns.

• Observed churn: 20.37% (2,037 records).

• Germany churn rate: 32.44%; France: 16.15%; Spain: 16.67%.

• Age 46–60 churn rate: 51.12%, highest among the defined age bands.

• Inactive member churn: 26.85% versus 14.27% for active members.

What it suggests

Geographic, age, activity and product-count segments merit closer review. The 3- and 4-product cohorts are small, so their high rates should be treated as signals for validation rather than stable population estimates. Average balance is not equivalent to profitability.

Recommended actions

• Investigate Germany-specific customer journeys and product/service issues.

• Pilot engagement interventions for inactive customers and measure incremental impact.

• Review customer needs for ages 46–60 without using age as a sole decision rule.

• Validate unusual product-count cohorts and data provenance.

• Create a governed monitoring dashboard with trend tracking, segment sizes and fairness checks.

Caveat

The supplied data source and representativeness are unverified. Results do not establish causation and should not be generalized to all European banks without further evidence.
